FLC10-200H/B

Application Specific Discretes
A.S.D.™

FIRE LIGHTER CIRCUIT

FEATURES

- Dedicated thyristor structure for capacitance discharge ignition operation
- High pulse current capability
  240A @ tp= 10µs
- Fast turn-on operation
- Designed for high ambient temperature (up to 120°C)

BENEFITS

- Space saving thanks to monolithic function integration
- High reliability with planar technology

IPAK
FLC10-200H

DPAK
FLC10-200B

DESCRIPTION

The FLC10 series has been especially developed for high power capacitance discharge operation. The main applications are gas lighters or ignitors such as :
cookers / gas boilers / gas hobs...

Based on ST's ASD™ technology, it provides a fully integrated function, with high performance and reliability levels, adapted to severe and hot temperature environment.
Th: Thyristor for switching operation.

Z: Zener diode to set the threshold voltage.

D: Diode for reverse conduction.

R: 2 kΩ resistor.

ELECTRICAL CHARACTERISTICS

Symbol	Parameters
V_{RM}	Stand-off voltage
V_{BO}	Breakover voltage
V_T	On-state voltage
V_F	Diode forward voltage drop
I_{BO}	Breakover current
I_{RM}	Leakage current
αT	Temperature coefficient for V_{BO}
DIODE (D) PARAMETER

Symbol	Test Conditions			Value	Unit
V_F	$I_F = 2A$ $tp \leq 500\mu s$	$Tj = 25°C$	Max.	1.7	V

THYRISTOR (Th) and ZENER (Z) PARAMETERS

Symbol	Test conditions		Min	Typ	Max	Unit
I_{RM}	$V_{RM} = 200$ V	$Tj = 25°C$			10	μA
		$Tj = 125°C$			100	μA
V_{BO}	at I_{BO}	$Tj = 25°C$	200	225	250	V
I_{BO}	at V_{BO}	$Tj = 25°C$			0.5	mA
V_T	$I_T = 2A$ $tp \leq 500\mu s$	$Tj = 25°C$			1.7	V
αT				13		$10^{-4}/°C$

Fig. 1: Relative variation of breakover current versus junction temperature.
k = IBO(Tj) / IBO(25°C)

Fig. 2: BASIC APPLICATION

The applications of the lighter using the capacitance discharge topology operate in 2 phases :

PHASE 1

The energy coming from the mains is stored into the capacitor C. For that, the AC voltage is rectified by the diode Ds.

PHASE 2

At the end of the phase 1, the voltage across the capacitor C reaches the avalanche threshold of the zener. Then a current flows through the gate of the thyristor Th which fires.
The firing of the thyristor causes an alternating current to flow through the capacitor C.
The positive parts of this current flow through C, Th and the primary of the HV transformer.
The negative parts of the current flow through C, D and the primaty of the HV transformer.

### COMPONENT CHOICE

RS RESISTOR CALCULATION

The Rs resistor allows, in addition with the capacitor C, the spark frequency to be adjusted and the current from the mains to be limited. Its value shall allow the thyristor Th to fire even in worst case conditions. In this borderline case, the system must fire with the lowest value of RMS mains voltage while the breakdown voltage and current of the FLC are at the maximum.

The maximum Rs value is equal to :

$$Rs \max = \frac{(V_{AC} \min . \sqrt{2}\ ) - [V_{BO} \max . (1 + \alpha\ T . (\ T_{amb} - 25\ ))]}{k\ .\ I_{BO}\ ^*}$$
* : see fig 1

Fig. 3: Spark frequency versus Rs and C
The couple Rs/C can be chosen with the previous curve. Keep in mind the Rs maximum limit for which the system would not work when the AC mains is minimum. The next curve shows the behavior with Rs=15kΩ and C=1μF.

**Fig. 4:** Voltage across the capacitance with Rs = 15kΩ, C = 1μF and V_{BO} = 225V.

PEAK CURRENT LIMIT

This component is designed to withstand I_{TRM} = 240A for a pulse duration of 10µs for an ambient temperature of 120°C in repetitive surge (see note 1, page 2).

The curve of peak current versus the pulse duration allows us to verify if the application is within the FLC operating limit.

**Fig. 5:** Peak current limit versus pulse duration.
POWER LOSSES (For 10µs, see note 1)

To evaluate the power losses, please use the following equations :

For the thyristor : $P = 1.18 \times I_{T(AV)} + 0.035 \, I^2_{T(RMS)}$

For the diode : $P = 0.67 \times I_{F(AV)} + 0.106 \, I^2_{F(RMS)}$
